USACE Sacramento District Datum Documentation Report

Project: Success Lake and Dam

NGVD 29To NAVD 88 Datum Conversion Factor: add 2.61 ft.

Datum Conversion Procedure: The USACE Mapping Unit and A-E Contractor performed field measurements with known historical elevations. All documentation and raw data is filed with the USACE Sacramento District Mapping Unit. All survey and gage control is in US feet and is tied to NGS monument AC6136. For questions or comments contact the Sacramento District Datum Coordinator. The results of this survey produced an averaged difference between NGVD 29 and NAVD 88 of 2.61 feet for the USACE Success Lake and Dam civil works project.

Station ID	COE-NGVD29 record	NAVD 88	Difference
AC6136 (KT 200)	696.97	699.60	2.63
52	671.03	376.64	2.61
59	584.77	587.36	5.59
56	656.91	659.52	2.61
			Average = 2.61
Averaged Delta = 2.61ft conversion factor			

Accuracy Statement: The NAVD88 datum conversion accuracy is: =/- 0.25 feet to real work NAVD 88 elevations per EC- 1110-2-6065 Comprehensive Evaluation of Project Datums. The stated conversion factor is for planning, operations, water management and legacy conversion only. All future design work and survey work shall adhere to the NAVD 88 datum and follow EM 1110-1-1005 Control and Topographic Surveying. Contact the USACE Sacramento District's survey unit or the district's datum coordinator for current survey control.

SUCCESS LAKE
TULE RIVER, CALIFORNIA

PERTINENT DATA

GENERAL

Drainage areas	
Tule River below Success Dam	393.0 sq. mi.
S. Fork Tule River near Success	109.0 sq. mi.
Tule River near Springville	247.0 sq. mi.
N. Fork of M. Fork Tule River near Springville	39.3 sq. mi.
Flows at dam site	
Mean annual (1904-1980)	137,400 ac-ft
Mean daily (1904-1980)	190 cfs
Max. mean daily recorded inflow (6 Dec 66)	40,000 cfs
Max. instantaneous recorded inflow (6 Dec 66)	76,900 cfs
Standard project peak inflow	67,500 cfs
Standard project peak outflow	43,650 cfs
Spillway design peak inflow	200,000 cfs
Spillway design peak outflow	126,000 cfs

RESERVOIR

Elevation	
Inactive pool	559.0 feet
Flood control pool (bottom)	587.0 feet
Gross pool	652.5 feet
Taking line	658.0 feet
Spillway design flood pool	686.8 feet
Area	
Inactive pool	83 acres
Flood control pool (bottom)	379 acres
Gross pool	2,477 acres
Taking line	2,832 acres
Spillway design flood pool	4,441 acres
Storage capacity	
Inactive pool	557 ac-ft
Flood control pool (bottom)	6,540 ac-ft
Gross pool (nominal capacity)	82,300 ac-ft
Standard project flood pool	130,000 ac-ft
Spillway design flood pool	202,700 ac-ft
Reservoir length at gross pool elev.	3.5 miles

SPILLWAY (Uncontrolled Broad-Crested)

Location	In saddle near right abutment
Crest length	200 feet
Crest elevation	652.5 feet
Total excavation	
Head at gross pool	3.26 feet
Head at spillway design flood pool	34.3 feet
Max. capacity (SDF pool)	126,000 cfs

MAIN DAM (Earthfill)

Elevation, top of dam	691.5 feet
Freeboard, above spillway design flood pool	4.7 feet
Maximum height	142 feet
Length of crest	3,490 feet
Width of crest	22.5 feet
Width of roadway	16.0 feet
Upstream slope	1 on 3.75; 1 on 3.0; 1 on 2.5 at crest
Downstream slope	1 on 3.0; 1 on 2.5 at crest
Total excavation	490,000 cu. yds.
Total volume of embankment	4,900,000 cu. yds.

FRAZIER DIKE (Earthfill)

Elevation, top of dike	691.5 feet
Freeboard, above spillway design flood pool	4.7 feet
Length of crest	7,650 feet
Width of crest	20 feet
Width of roadway	16 feet
Maximum height	42 feet
Upstream slope	1 on 2.75
Downstream slope	1 on 2.75
Total excavation	67,000 cu. yds.
Total volume of embankment	660,000 cu. yds.

MAIN OUTLET

Conduit (concrete-lined tunnel)	
Diameter	12.0 feet
Intake structure elev., invert	559.0 feet
Outlet elev., invert	551.0 feet
Length	687.0 feet
Gates (number and size)	
Service gates (hydraulically operated slide)	2 - 5'8" x 10'0"
Emergency gates (hydraulically operated slide)	2 - 5'8" x 10'0"
Total capacity of outlets with water surface	
At elev. 587.0 (6,540 ac-ft)	3,200 cfs
At elev. 652.5 (82,300 ac-ft)	6,300 cfs

PIONEER IRRIGATION DITCH OUTLET

Steel pipe (concrete encased)	
Diameter	42 inches
Length	687.0 feet
Gross head	103.5 feet
Gates (number and size)	
Service gate (double disc type gate valve)	1 - 42" diameter
Emergency gate (double disc type gate valve)	1 - 42" diameter
Total discharge capacity (full valve opening)	
At elev. 560.0 (91 ac-ft)	75 cfs
At elev. 652.5 (82,300 ac-ft)	284 cfs

NOTICE TO USERS OF THIS MANUAL

Regulations specify that this Water Control Manual be published in looseleaf form, and only those sections, or parts thereof, requiring changes will be revised and printed. Therefore this copy should be preserved in good condition so that inserts can be made to keep the manual current.

I - INTRODUCTION

1-01. Authorization. The Success Lake Water Control Manual, Tule River, California, is an Appendix to the Tulare Lake Basin Master Water Control Manual. It is prepared in accordance with instructions contained in EC 1110-2-208; EM 1110-2-3600, and ETL 1110-2-251.

1-02. Purpose and Scope. This manual provides a detailed plan for water control and management at the Success Lake project on the Tule River, California.

1-03. Related Manuals and Reports. This manual is Appendix IV to the Tulare Lake Basin Master Water Control Manual. Other related reports are as follow:

1-04. Project Owner. Success Lake is owned by the U.S. Government.

1-05. Operating Agency. The Sacramento District, U.S. Army Corps of Engineers operates Success Lake. Duties related to the control of outflows are performed by the Park Manager or by a designated Damoperator. The Park Manager has a normal tour of duty at the dam of eight hours per day, five days a week. At other times, the Park Manager may be contacted at his residence at the project. Project personnel will be on duty weekends and holidays and at other-than-normal working hours as necessary for effective

project operation. Operational responsibilities are explained in detail in Exhibit A. Business and home phone numbers of the individuals responsible for project operation are given at the beginning of this manual and at the beginning of Exhibit A.

1-06. Regulating Agencies. The operation plan for Success Lake for flood control was developed by the Corps of Engineers, Sacramento District, with the objective of gaining the greatest possible benefits from flood control, irrigation and recreation.

Releases for purposes other than flood control are directed by the Tule River Watermaster who represents the Pioneer Water Company, the Vandalia Irrigation District, Porterville Irrigation District, the Lower Tule River Irrigation District and the downstream Kaweah River and Tule River Associations. These organizations are known collectively as the Tule River Association. The Watermaster's work and home phone numbers are listed at the beginning of this manual and at the beginning of Exhibit A.

II - DESCRIPTION OF PROJECT

2-01. Location. Success Lake is located on the Tule River, California, about 6 miles east of Porterville, California. The project can be reached by driving east from Porterville on State Highway 190. Its location is shown on plate 1.

2-02. Purpose. Success Lake provides storage for flood control, conservation and other purposes.

2-03. Physical Components. The Success Project consists of a dam and reservoir on the Tule River. It intercepts the runoff from 391 square miles of mountainous area. Pertinent data for the project are tabulated at the front of this manual. A general site plan and recreation development are shown on plate 2. Success Dam is an earthfill structure with a maximum height of 142 feet and a length of 3,490 feet. The top of the dam at elevation 691.5, provides 4.7 feet of freeboard above the spillway design flood pool at elevation 686.8 feet. A plan and profile of the dam are shown on plate 3.

A rolled earthfill dike known as Frazier Dike, 42 feet high and 7,650 feet long extends across Frazier Valley about 3-1/2 miles northwest of the dam. A plan, profile and sections are shown on plate 4.

At normal full pool (elevation 652.5), the reservoir extends about 3.5 miles from the dam in an easterly direction. The capacity of Success Lake at normal full pool was originally 85,400 acre-feet, but sedimentation has reduced it to about 82,300 acre-feet. The area at normal full pool is about 2,477 acres. Area and capacity curves are presented on plate A-1, and a table of areas and capacities is presented on plate A-2.

The outlet works consist of one 12-foot circular conduit-type gated outlet with intake invert elevation at 559 feet and one 42-inch gated concrete-encased steel pipe under the main conduit, with invert elevation at 553 feet. The main outlet is controlled by two 5'8" x 10'0" hydraulically operated slide gates (with two 5'8" x 10'0" hydraulically operated emergency slide gates) and has a capacity of 3,200 c.f.s. at elevation 587 feet, at which the storage is 6,540 acre-feet. The rating curves for various gate openings for this outlet are shown on plate A-3. The smaller outlet takes off from the main outlet upstream from the slide gates. It is controlled by a 42" diameter double disc type valve service gate (with similar emergency gate) and has a capacity of 75 c.f.s. at pool elevation 560 feet, or 284 c.f.s. at gross pool elevation of 652.5 feet. This outlet serves Pioneer Irrigation Ditch which formerly diverted water from Tule River upstream from the damsite. A rating curve for Pioneer Ditch is shown on plate A-5. A plan, profile and sections of the control tower and outlet works are shown on plates 5 and 6.

The spillway is ungated and is excavated through overburden into the rock of a natural saddle about 900 feet from the right abutment of the main dam. It has a crest width of 200 feet and a safe discharge capacity of 126,000 cubic feet per second when the reservoir water surface is at spillway design flood pool (elevation 686.8 feet). A plan, profile, and sections of the spillway are shown on plate 7 and a rating curve is shown on plate A-4.

TABLE 2-01

RECREATION FACILITIES AT SUCCESS LAKE

Area	Camp Sites	Picnic Sites	Launch Lanes	Restroom Facilities: Flush	Vault	Portable 1/	Parking: Car	Car-Trailer
Observation					1		20	
Tule	104 2/	31 3/	6 4/	7		24	50	200
Gill						6	160 5/	
Wildlife						2		
Rocky Hill	223 5/		2	1		24	50	125
Bartlett Park		54 6/		4				

NOTES:
1/ Average. (More may be added if demand indicates).
2/ Includes 2 sites reserved for handicapped use.
3/ Includes 6 group sites (each group site will accommodate 20+ people).
4/ Six lanes available for high lake levels - 3 for low lake levels.
5/ Primitive.
6/ Includes 12 group sites. Group sites consist of 6 sites accommodating over 150 persons, and 6 sites accommodating 40-60 persons.
7/ Approximate figure. Parking is random along side of roads.

2-04. Related Control Facilities. The Success Project consists of the dam and reservoir and appurtenant facilities. No other improvements outside the reservoir area were made under the authority of this project. However, local interests have made channel improvements downstream.

2-05. Real Estate Acquisition. Project lands consist of approximately 4,116 acres acquired in fee, 57.8 acres under easement, and 0.2 acres under lease or permit. The minimum take line for this land is at elevation 658. The project land boundaries are shown on plate 2.

2-06. Public Facilities. Most recreation use of Success Lake presently occurs in and originates from the developed south and west shores of the lake and at Bartlett Park. Some use occurs at the undeveloped Gill area and in the partially developed wildlife management area. Success Lake has one of the best bass fisheries in the San Joaquin River Basin. Other recreation at Success Lake includes picnicing, camping, waterskiing, hunting, swimming, pleasure boating and sightseeing. In addition, opportunities for specialized activities such as hunting dog trials and horseback riding are also provided. Recreation facilities currently available at Lake Success are listed on Table 2-01 and the locations are shown on plate 2.

Accurate visitation records have been kept for Success Lake since 1964 when 603,200 recreation days were recorded. Annual visitation from 1964 through 1980 is as follows:

TABLE 2-02
ANNUAL VISITATION AT SUCCESS LAKE

1964	603,200
1965	568,050
1966	565,990
1967	400,960
1968	590,430
1969	533,300
1970	627,450
1971	549,890
1972	514,200
1973	691,340
1974	615,450
1975	775,280
1976	724,440
1977	696,750
1978	801,750
1979	569,840
1980	933,500
Mean	633,000

III - HISTORY OF PROJECT

3-01. Authorization. The investigation which led to the recommendation to construct Success Lake was authorized 22 June 1936. The project was authorized for construction by the 22 December 1944 Flood Control Act as follows:

> "The Plan for Terminus and Success Reservoirs on the Kaweah and Tule Rivers for Flood Control and other purposes in the San Joaquin Valley, California, in accordance with the recommendations of the Chief of Engineers in Flood Control Committee Document Number 1, Seventy-eighth Congress, Second Session, is approved, and there is hereby authorized $4,600,000 for initial and partial accomplishment of the plan."

3-02. Planning and Design. In Committee Document Number 1, 78th Congress, 2nd Session, dated 1944, the Chief of Engineers recommended a reservoir capacity of 50,000 acre-feet. However, subsequent studies made for the basic report indicated that, to provide adequate flood control, the storage capacity should be 115,000 acre-feet. The State of California and Tulare Lake interests questioned the economic feasibility of this increase. This is noted in the District Engineers report to the Chief of Engineers dated 1 June 1948. The report is in House Document 367, 81st Congress, 1st Session dated 1950.

Further investigations were made, and by letter of 6 July 1949, subject: "Preliminary Definite Project Report, Success Project, Tule River, California," the District Engineer transmitted a report recommending a capacity of 75,000 acre-feet, on the grounds that such capacity was necessary for flood control and that a larger capacity was not economically justified. The 75,000 acre-foot capacity was approved by the Chief of Engineers in 2nd endorsement dated 5 August 1949 to the basic letter of 6 July 1949. At a conference between representatives of OCE, SPD and the Sacramento District on 9 May 1956 it was decided to provide an additional 5,000 acre-feet of capacity for sedimentation reserve, which increased the planned total gross pool capacity to 80,000 acre-feet.

3-03. Construction. Construction funds were initially appropriated in fiscal year 1957 but relatively little was accomplished until fiscal year 1959 due to inadequacy of authorized funds. Construction on the main dam and appurtenances was begun during October 1958. Closure of the dam was initiated 4 April 1960 and was completed 20 January 1961. The project was certified complete and accepted by the Government for operation on 15 May 1961. State Highway 190 and the county road were relocated.

3-04. Related Projects. Success Lake is part of a system of reservoirs providing flood protection to Tulare Lakebed and adjacent areas. The other reservoirs are Pine Flat Lake, Lake Kaweah, and Isabella Lake. Kaweah River water may enter the Tule River via Elk Bayou.

The Friant Kern Canal crosses the Tule River approximately eleven miles downstream from Success Dam. It delivers irrigation water to the Tule River and has the potential to export flood waters if necessary.

Upstream and downstream control structures are discussed in paragraphs 4-10 and 4-11.

3-05. Modifications to Regulations. The flood control diagram in the original flood control manual dated June 1961 was based on a total reservoir capacity of 80,000 acre-feet: 75,000 acre-feet for flood control during the rain flood season and 5,000 acre-feet, below elevation 587, for silt and recreation purposes. However, after the project was constructed, it was found that the reservoir contained more than 80,000 acre-feet at gross pool (elevation 652.5). A November 1965 survey showed that the reservoir capacity at gross pool was actually 85,400 acre-feet and that 6,800 acre-feet of this capacity was below elevation 587. Since certain recreation facilities were installed based on that elevation it was decided to make the silt and recreation pool 6,800 acre-feet. The additional 3,600 acre-feet of space above elevation 587 was designated as winter flood control reservation when necessary to compensate for any decrease in irrigation and spreading demands. Additional surveys were made in 1978. The flood control diagram dated July 1981 in this manual is based on the 1978 survey. The current gross pool storage is 82,300 acre-feet and the storage below elevations 587 is 6,540 acre-feet.

The lines delineating the flood control space requirements during the rainflood season have been altered on the July 1981 diagram to more accurately portray the period of rainflood hazard.

The snowmelt operation requirements have been changed on the July 1981 diagram based on past operating experience and hypothetical routings of snowmelt floods (1906 to 1981). The objective of the snowmelt operation requirements is to minimize releases in excess of irrigation and spreading demand.

3-06. Principal Regulation Problems. Since completion of Success Lake, there have been no principal regulation problems. However, several large floods which included the largest rainflood of record (December 1966) and the second largest snowmelt flood of record (April-July 1969) have occurred. Operations during these floods demonstrated that Success Lake does not provide the degree of protection as presumed during the design stage. Discussions of these floods are covered in paragraphs 8.02c and d. Another potential regulatory problem is the high rate of sediment buildup in the reservoir. Sediments are accumulating at about twice the 1956 projected rate. Current projected deposition rates indicate that gross pool storage will be less than 75,000 acre-feet by the year 2020. Sediment deposition has a compound effect on the project by reducing available space for flood control, conservation, and recreation usage.

IV - WATERSHED CHARACTERISTICS

4-01. General Characteristics. The watershed above the dam is a fan-shaped mountainous area of about 391 square miles on the western slope of the southern Sierra Nevada. The Tule River is formed by three main forks flowing from the high eastern border of the basin in a southwesterly or westerly direction to their junction near the foothill line. The North, Middle, and South Forks are fed by numerous small streams with slopes ranging from 400 to about 1,000 feet per mile. The soil cover below 9,000 feet elevation ranges from moderate to deep. Vegetal cover is distributed approximately as follows:

TABLE 4-01

VEGETAL COVER ON TULE RIVER BASIN

Description	Elevation (ft. msl)	Percent of Basin Area
Grass lands (with scattered brush)	500- 3,000	9.3
Brush lands (chaparral, etc.)	2,500- 9,000	17.0
Deciduous forest (with brush, scattered conifers, and grass)	500- 7,000	48.9
Light coniferous	5,000-10,000	19.6
Heavy coniferous	6,000- 8,000	4.3
Sub-alpine forest	8,000-10,000	0.5
Bare rock	8,000-10,000	0.4
TOTAL		100.0

The area is sparsely settled and suitable for grazing, lumbering, mining, and recreation. More than half of the basin is within the Sequoia National Forest, and the southern portion of it comprises the Tule River Indian Reservation. The Tule River flows about 3 miles through low foothills below Success Dam and emerges on the valley floor near Porterville. There are no major tributaries between Success Dam and Porterville, the major potential damage area below the project. Porterville is located on the right bank of the Tule River.

Below Porterville the area becomes predominately agricultural along the river to Tulare Lakebed where the river terminates. Normally, diversions for agriculture cause the river to dry up before it gets to the lakebed.

4-02. Topography. The area above the dam is steep mountainous terrain. Below the dam there are foothills which transition into an alluvial fan and flatlands gently sloping to Tulare Lakebed. Elevations range from about 10,000 feet in the mountains to 550 feet at the dam, 450 feet at Porterville and down to 175 feet in Tulare Lakebed. The percent of area above various elevations is shown below:

TABLE 4-02

PERCENT OF AREA ABOVE GIVEN ELEVATIONS
IN TULE RIVER BASIN

Elevation (feet)	Percent of Area Above Elevation
550	100
2,000	75
4,000	45
5,000	33
6,000	22
8,000	5
10,050	0

A topographical map is shown on plate 8, an area elevation curve is shown on plate 9, and a stream profile is shown on plate 10.

4-03. Geology and Soils. The intrusion of the Sierra Nevada Batholith through metamorphased sediments has created a complicated rock structure in the Tule River Basin. Glacial and stream erosion have cut deeply leaving large areas of exposed granite and roof pendants of metamorphased rock. Alluvial deposits cover the narrow canyon floors and the wide alluvial fan where the Tule River emerges from the foothills onto the San Joaquin Valley floor. Lake deposits are found at the rivers terminus in Tulare Lakebed.

A number of minor faults are located within the basin area. Major faults nearby include the Garlock and San Andreas faults, within 90 miles, White Wolf fault within 75 miles and the Sierra Nevada and Pond-Poso faults within 50 miles.

4-04. Sediment. Storage space below elevation 587 feet has been reserved for sedimentation. A system of 27 sedimentation ranges was established by ground survey methods before reservoir operation was initiated. Two of these ranges cross the river below the dam, two above gross pool elevation on the river; and the remaining ranges are so spaced that no range represents more than 10 percent of the potential sediment accumulation in the reservoir. Each range is straight and is marked by a permanent monument above gross pool at each end. Each profile is recorded on a permanent drawing to a horizontal scale of 1 inch to 20 feet, with an attached table showing the coordinates of all survey points. The range locations are shown on plate 11. Reconnaissance surveys of the sedimentation ranges are made as deemed necessary; generally after major events. General surveys of the reservoir area have been made in 1960, 1965, 1967, 1968, 1973 and 1977. The surveys show that approximately 186 acre-feet of sediment per year has accumulated in Success Lake. In addition to surveys of the reservoir area, the sediment concentration of outflow from the reservoir is measured each month or at intermittent intervals from a one-gallon sample of outflow water taken immediately below the outlets of the dam. An estimate of sediment outflow of 4 acre-feet per year was computed from the 20 year record of outflow volume and the concentration of solid sediment indicated by sample measurements.

4-05. Climate. The valley area is characterized by hot, dry summers and moderate winters. At high elevations the summers are cool and the winters severe.

a. Temperature. Temperatures within the basin vary considerably. On the valley floor the summer highs go well over 100°F. while the winter lows may go below freezing. At the higher elevations, the summer highs are generally less than 100°F. while the winter lows may go below 0°F. The mean monthly and annual temperatures at three stations within or near the Tule River Basin are shown below:

TABLE 4-03

MEAN MONTHLY AND ANNUAL TEMPERATURES (°F)

Month	Success Dam (elev. 590)	Grant Grove (elev. 6600)	Three Rivers Edison PH #2 (elev. 950)
Oct	66.0	49.9	64.2
Nov	54.7	40.5	53.9
Dec	46.3	35.3	47.2
Jan	46.1	33.2	46.3

b. Precipitation. Normal annual precipitation (NAP) in the Tule River Basin varies from about 6-inches at the lowest elevation to about 50-inches at the headwaters. The NAP for the Basin above Success Reservoir is 31.0 inches. NAP isohyets for the area are shown on plate 12. Approximately 90 percent of the precipitation occurs in the period from November through April. It generally occurs as rain below 5,000 feet and as snow above that elevation. However, warm winter storms have produced rain up to 11,000 feet, which would cover the entire basin, and snow has occurred on the valley floor below the dam. The average monthly precipitation for representative stations is shown below:

TABLE 4-04

c. Snow. Snow cover below 5,000 feet is generally transient and may accumulate and melt a number of times during the winter season. Above 5,000 feet, the snow generally accumulates until March when the melt season begins. Snowpack data for 1969, 1975, and 1977 representing wet, normal, and dry years is shown below:

TABLE 4-05

1 APRIL SNOW PACK DATA FOR 1969, 1975 AND 1977

Total	12,724	

1/ Average for 1964-1981 period.

4-06. Storms and Floods. Flood flows on Tule River are of two types, winter rain floods and spring snowmelt floods. The winter-type floods are characterized by sharp high peaks and small volumes and are usually of short duration, seldom lasting more than four days. These winter floods normally occur during the period November through March and are caused by intense rains sometimes augmented by snowmelt at the lower elevations. The largest rain flood of record on Tule River at Success Dam was that of December 1966. Flows during the 6 largest rain floods of record follow:

TABLE 4-08
MAXIMUM INFLOW TO SUCCESS LAKE

Date of Peak	Peak (Average Flow in c.f.s)	Peak 1-Day	Peak 3-Day	Peak 7-Day	Peak 15-Day	Peak 30-Day
6 Dec 1966	76,900	40,000	18,300	8,700	4,300	2,300
19 Nov 1950	28,000*	15,500*	8,100*	3,700*	2,100*	1,100*
23 Dec 1955	27,000	13,600	6,100	3,300	1,800	1,000

9 Mar 1943	21,000*	14,200*	8,600*	4,400*	3,700*	2,700*
3 Jan 1980	17,000	8,700	7,200	4,100	2,300	1,600

*Determined by correlation with Tule River near Porterville.

Flows during the 5 largest snowmelt floods of record follow:

TABLE 4-09

MAXIMUM INFLOW TO SUCCESS LAKE DURING SNOWMELT SEASON

Water Year	1-Day	15-Day	30-Day	60-Day	90-Day	120-Day
	(Average Flow in c.f.s.)					
1906	3,560*	2,100*	1,920*	1,700*	1,690*	1,330*
1969	1,560	1,270	1,220	1,200	1,000	830
1938	1,650*	1,160*	1,140*	1,050*	1,040*	800*
1909	1,270*	1,180*	1,120*	1,020*	1,000*	780*
1967	1,740	1,250	1,080	980	840	690

*Determined by correlation with Tule River near Porterville.

4-07. Runoff Characteristics. Stream gage locations are shown on plate 8, a stream profile is shown on plate 10 and historical unimpaired flow below Success Dam is shown on plate 13. The flows on plate 13 from 1904 through 1953 have been estimated based on upstream gages. Runoff data at 3 of the upstream gages follows:

TABLE 4-10

RECORDED RUNOFF DATA

	Tule River near Porterville	Tule River near Springville	SF Tule River

1/ Average for 1904-1980 period.

4-08. Water Quality. The quality of Success Lake water, its inflow, and its outflow are checked bi-annually in April and August. A probe is used for on-site determination of temperature (T), dissolved oxygen (D.O.), pH, and electrical conductivity (EC). Nutrient, algae, salt, heavy metal, and pesticide levels are determined from samples in a laboratory. A sample measurement follows:

TABLE 4-12
WATER QUALITY OF TULE RIVER - APRIL 16, 1974

Location	Inflow	Lake	Outflow
Flow (c.f.s.)	289		303
TC (°F)	62	59	54.4
E.C. (p.p.m.)	142	120	166
D.O. (p.p.m.)	8.5	8.7	10.1
p^H	7.8	8.4	7.3

In general, the project water quality is good to excellent relative to its beneficial uses. They have been determined by the State of California to be:

TABLE 4-13

BENEFICIAL USES OF TULE RIVER WATER

Success Lake	Downstream
Recreation	Recreation
Warm freshwater habitat	Warm freshwater habitat
Wildlife habitat	Wildlife habitat
Freshwater replenishment	Groundwater recharge
	Municipal and domestic supply
	Agricultural supply
	Industrial service supply
	Industrial process supply

4-09. Channel and Floodway Characteristics. Channel capacities below Success Dam are shown on plate A-7. Immediately below the project the channel passes through relatively sparsely populated rolling hills for about 5 miles before reaching Porterville. This reach can pass about 10,000 c.f.s. to below Porterville before agricultural damages occur and about 16,000 c.f.s. before damage occurs to urban property. Porter Slough takes off from the Tule River just above Porterville and passes through the Porterville business district. Its capacity is about 180 c.f.s. and diversions to it are controlled by a concrete structure.

Below Porterville the Tule River flood plain is mainly agricultural and the channel capacity decreases in this area. About 22 miles downstream from Porterville, Elk Bayou enters the Tule River and may contribute Kaweah River water. Tule River flow essentially enters Tulare Lakebed at Turnbull Weir where any remaining flow must be diverted into Lakeland Canal or it will enter the lakebed.

Since the Tule River has no outlet to the ocean, any releases above irrigation and spreading capability may be damaging below Turnbull Weir. In the spring and summer months, irrigation and spreading demand may reach approximately 1,500 c.f.s.: 1,000 c.f.s. diverted and 500 c.f.s. spread within the channel. During the rainflood season, under optimum conditions, the diversion capability may reach 500 c.f.s. and in channel spreading capability another 500 c.f.s. for a total of 1,000 c.f.s. above Turnbull Weir. At Turnbull Weir, up to 300 c.f.s. can be diverted into the Lakeland Canal depending on canal inflow from Elk Bayou (Kaweah River distributary) and other sources and the conditions at the canal's terminus. Channel improvements are in progress to increase Lakeland Canal to 550 c.f.s. by 1984.

In the past, releases of 3,200 c.f.s. (the maximum project design release) have caused damage to agricultural areas. In December 1966 a combined spill and release of 9,050 c.f.s. caused considerable agricultural damage but very little damage to urban property.

4-10. Upstream Structures. There are two powerhouses above Success Lake: Tule Powerhouse owned by P.G.&E. on the North Fork of Middle Fork Tule River and Tule Powerhouse owned by S.C.E. on Middle Fork Tule River. Larson Dam wit 325 acre-feet of storage is located on a tributary to the South Fork Tule River and a diversion to South Tule Ditch is located on the South Fork Tule River. None of these projects affect the operation of Success Lake.

4-11. Downstream Structures. Except during large floods, most releases from Success Lake are used for irrigation. There are numerous diversion structures downstream for this purpose. Their locations are shown on plate A-7. The structure at the head of Porter Slough just above Porterville is of particular importance since it prevents excessive flow from going into Porter Slough and flooding Porterville.

4-12. Economic Data.

a. Population. Porterville is the only major population center along the Tule River. Its population is approximately 20,000. It is located in Tulare County which has a population of approximately 230,000.

b. Agriculture. Agriculture is the major activity along the Tule River. The crops grown include citrus, grapes, cotton and cattle field crops.

c. Industry. Manufacturing does take place in the vicinity of Porterville. The classes of goods manufactured include electronics, printing, synthetic yarns, womens sportswear, marine controls, disposable diapers, helicopters and machine components.

d. Flood Damages. Rainfloods on the Tule River produce high peak flows which damage improvements within the channel and adjacent areas while the volume exceeding irrigation and spreading capabilities goes on to Tulare Lake to pond on cropland. Prior to construction of Success Lake, rainfloods frequently caused extensive soil erosion, damaged farm equipment and structures, silted in irrigation canals, washed out diversion structures and washed out reaches of highways. The December 1950 flood, which reached a peak of approximately 28,000 c.f.s. at the Success Dam site, extensively damaged agricultural and industrial areas and caused relatively shallow flooding in a small portion of Porterville. The December 1955 flood, which peaked out at approximately 25,000 c.f.s. at the damsite, caused extensive damage but did not flood Porterville or its suburbs.

Snowmelt floods have much lower peak flows than rainfloods but larger volumes. Tule River snowmelt flood flows combined with runoff from adjacent basins flood large areas in Tulare Lakebed for long periods of time, more than a year in some cases.

A number of large floods have occurred since the project was built, the December 1966 flood with a peak inflow to Success Lake of 76,900 c.f.s. being the largest of record. Its combined spill and release reached 9,050 c.f.s. This flow damaged agricultural areas along the Tule River and in Tulare Lakebed but did relatively little damage to urban areas. The estimated damages prevented by Success Lake during 4 major floods follow:

TABLE 4-14
ESTIMATED DAMAGES PREVENTED BY SUCCESS LAKE

Water Year	Damages Prevented ($1,000)	
	During Rainfloods	During Snowmelt Floods
1967	10,400	1,280
1969	5,300	2,100
1978	5,490	380
1980	7,600	1,500

V - DATA COLLECTION AND COMMUNICATIONS NETWORKS

5-01. Hydrometeorological Stations. Hydrometeorological information at Success Lake and elsewhere within the Tule River basin is monitored through the Hydrologic Automatic Data Acquisition (HADA) system. The Success Lake project office subcentral station automatically stores precipitation reports from 4 gages, Hossack (Hossack also transmits temperature data), Eagle Creek, Rogers Camp and Mountain Home by radio. It also automatically stores project release data and reservoir stages. Temperature, wind, evaporation and precipitation data at the project is entered into the subcentral station memory manually with thumb wheels. This data is transmitted to the central station (HADA central) in the Sacramento District Reservoir Control Section office. Normally, the precipitation gages automatically report every 6 hours, however, the system is set to make interim reports when .3 inches or more of precipitation falls since the last report.

The facilities at the project include the following:

a. A float operated digital recording pool gage in the dam capable of recording pool levels up to the spillway design pool level, supplemented by a permanent staff gage in the reservoir.

b. Two float operated digital recording outflow stream gages with selsyn operated data transmission just below the dam. One of these gages is on Tule River and the other is on Pioneer Ditch. Both are supplemented with visual staff gages.

c. Recording inflow stations on Tule River near Springville and on South Fork Tule River near Success above the reservoir.

d. A weather station at the dam.

The weather station at the dam consists of:

a. Recording and non-recording precipitation gages.

b. A wind station recording both direction and velocity.

c. A weather bureau Class-A evaporation pan with anemometer.

d. A recording hygrothermograph with maximum and minimum thermometers.

Climatological station locations and descriptions are shown on plate 12 and stream gage locations and descriptions are shown on plate 8.

5-02. Water Quality Stations. Project water quality and the techniques used to monitor it are discussed in paragraph 4-08. The locations and descriptions of water quality stations are shown on plate 8.

5-03. Sediment Stations. The sedimentation range locations are shown on plate 11. Reservoir sedimentation is discussed in paragraph 4-04.

5-04. Recording Hydrologic Data. Records of storage, inflow, outflow and evaporation at Success Lake are kept at the Corps of Engineers District Office

in Sacramento. Outflows and storages for the project are published by the U.S. Geological Survey from the Corps record. Extensive hydrologic data pertinent to irrigation is published by the Tule River Association.

5-05. Communication Network. Voice communication between the Sacramento Office and the project office is either by radio or telephone and the radios in both offices have backup power from batteries and standby generators.

The central station of the Hydrologic Automatic Data Acquisition system (HADA) in Sacramento can interrogate the subcentral stations of the projects by radio or telephone. The central and subcentral stations have backup power from batteries and standby generators.

The precipitation and stream gaging stations above the project report to the subcentral station by radio only and the reservoir stage and outflow gages are hard wired to the HADA system.

5-06. Communication with Project. Communication requirements between the project office and the Reservoir Control Section are discussed in exhibit A.

5-07. Project Reporting Instructions. Reporting instructions are discussed in exhibit A.

5-08. Warnings. Warnings are discussed in exhibit A.

VI - HYDROLOGIC FORECASTS

6-01. General. Since reliable long-term rainflood forecasts are not available, the rainflood space must be kept available throughout the rainflood season in anticipation of a large unforecasted rainflood. Short-term precipitation forecasts are available and are mainly useful for anticipating release changes due to increased inflow or a change in downstream conditions.

Most of the central valley in California is relatively unique in that general rainfloods during the late spring and summer are extremely rare. Therefore, runoff into the reservoirs can be fairly accurately predicted during the spring and summer based on the snowpack in the mountains. This allows the space required for flood control to be varied during the snowmelt season based on the forecasted runoff. These snowmelt forecasts are important in optimizing reservoir operation for flood control and conservation.

a. Role of Corps. The Corps of Engineers has no responsibility for furnishing forecasts of flow into or out of Success Lake to the public. However, the Corps does furnish release predictions to the National Weather Service to facilitate their forecasting of river flows. Plate 14 provides data which can be used to forecast inflow due to rain based on precipitation or known inflow.

b. Role of Other Agencies. The National Weather Service provides precipitation and river flow forecast data and the State provides snowmelt forecasts.

6-02. Flood Condition Forecasts. The National Weather Service provides short-term local precipitation forecasts up to 24-hours in advance. The precipitation gages incorporated in the HADA system which report every 6 hours under normal conditions will make interim reports anytime .3 inches of rain has fallen since the last report.

Since the conditional space required for flood control is determined from snowmelt forecasts, they are of primary concern in the operation of Success Lake. The Tule River Watermaster and the Corps of Engineers use snowmelt forecasts made by the California Department of Water Resources. The Department prepares forecasts of April through July runoff into Success Lake as of 1 February, 1 March, 1 April, and 1 May each year. Weekly updates are provided when conditions change appreciably from the last forecast. The forecasts are published about 10 days after the date to which they apply. A summary of forecasted runoff compared to actual runoff is shown on plate 15.

6-03. Conservation Purpose Forecasts. Operation of Success Lake for conservation is generally as requested by the Tule River Watermaster. The total demand for conservation water in Success Lake is largely a function of the forecasted runoff during the snowmelt season. Normal irrigation demand is shown on plate A-8.

6-04. Long-range Forecasts. Other than snowmelt forecasts discussed above, no long-range forecasts are used by the Corps of Engineers for the Tule River basin.

VII - WATER CONTROL PLAN

7-01. General Objectives. Success Reservoir will be operated for flood control and conservation to achieve the following objectives:

a. To restrict flows in downstream channels of Tule River and its distributaries to nondamaging rates.

b. To minimize damaging flows from Tule River into the Tulare Lakebed area.

c. To provide the maximum practicable amount of storage space for conservation of irrigation water without impairment of the flood control functions.

7-02. Major Constraints. Releases greater than irrigation and spreading demand have the potential to pond on valuable cropland in Tulare Lakebed. Tulare Lakebed also receives flood water from a number of other sources. * Therefore, releases from Success Lake should be coordinated with flow from * other sources to the extent possible giving consideration to downstream * storage and diversion capabilities. *

Structures which impede the flow of water over the spillway will not * be permitted. *

7-03. Overall Plan for Water Control. The overall plan for water control is to coordinate releases for flood control with conservation demand to the greatest extent possible. During the rainflood season, when reliable inflow forecasts are not available, the required rainflood space is set for a given date, with minor variations based on downstream irrigation and spreading capability, and antecendent precipitation. During the snowmelt season, the required flood control space is varied based on forecasted inflow and irrigation and spreading demand to satisfy both flood control and conservation objectives. The snowmelt portion of the flood control diagram (plate A-8) is designed to fill the reservoir, if runoff and irrigation demand permit, but not to spill.

Downstream spreading and irrigation capability is essential to allow * non-damaging releases to be made. The design of Success Lake flood control * operation is based on maintaining a 500 c.f.s. irrigation and spreading * capability along the Tule River below the project. *

7-04. Standing Instructions to Dam Operator. The standing instructions to the dam operator are contained in exhibit A.

7-05. Flood Control. In 1986, the Tule River Association agreed on the * following to describe the distribution of water released from flood control * space: "Water stored in schedule 1, 2, or 3 flood control space will be * released in accordance with the schedule that applies to that space. These * criteria are established to ensure the timely release of water from flood * control space in the reservoir and, therefore, such releases shall not be * restricted by the storage and diversion rights under the Tule River * Association agreements. It is understood that, under the Tule River * Association agreements, each TRA unit has the right to supplement any * required flood control releases by additional releases of such unit's Tule *

River Water entitlement and/or water held in Success Lake storage for the account of such unit, as may be desired from time to time for beneficial use by such unit."* A detailed explanation of flood control operation, including emergencies, is contained in exhibit A and on plate A-8. An explanation of the allocation of reservoir space is contained in paragraph 3-05, "Modification to Regulations". Specific information concerning forecasts and channel and floodway characteristics is found under those headings.

7.06. Recreation. On 2 November 1965, the Tule River Association entered into an agreement with the County of Tulare (Tulare County Agreement No. 1915) for the purpose of providing a minimum pool for recreational use. This agreement was terminated on 16 October 1987 and the parties are presently negotiating a new agreement.

7.07. Water Quality. Success Lake is not operated for water quality. Water quality measurements and the quality of water within the Lake are discussed in paragraph 4-08, "Water Quality."

7-08. Fish and Wildlife. Success Lake supports one of the best bass fisheries in the San Joaquin Basin. In addition, approximately 1,400 acres on the northeast side of Success Lake have been set aside as a wildlife management area. About half of the acreage is above gross pool elevation. The area is characterized by alternating rows of bush, cereal grains, and fallow strips. The area is managed to increase the variety and numbers of upland game species as well as non-game animals. The area was developed with the assistance and cooperation of the California Department of Fish and Game, Southern Tulare Sportsmen's Association, Tulare County Audubon Society, California Department of Forestry, Tulare County Fine Commission, and Tulare County Parks and Recreation Department.

7.09. Water Supply. Space not required for flood control or retention of a minimum pool is operated for conservation. In 1986, the Tule River Association agreed on the following to describe the distribution of water stored in conservation space: "Water stored in conservation space may be released by Tule River water users in accordance with their respective entitlements under the agreements among such water users."

User contract No. 14-06-200-2110A between the United States and the downstream water users provides for the operation and maintenance of irrigation space.

7-10. Hydroelectric Power. There are no facilities for hydroelectric power generation at this time, however, the Lower Tule River Irrigation District representing the Tule River Association has an approved application from F.E.R.C. for generating power at the project.

7-11. Navigation. No portion of the Tule River is considered navigable.

7-12. Drought Contingency Plan. During droughts, flood control is not expected to be a principle factor in the operation of Success Lake. Conservation water and conservation space is managed by local interests in accordance with contacts between the various irrigation interests. As part of the drought contingency plan, Schedule 1 releases may be deferred temporarily in anticipation of a dry water year during the period 11 November through 27 March. The amount of encroachment at anytime is dependent on the basin

wetness parameter as discussed in paragraph 3f in exhibit A. During droughts, the Tule River Watermaster and the various groups he represents can be expected to conserve water to the best of their ability. Any information that the Corps of Engineers may have that would be beneficial to drought operation will be passed on to the Tule River Watermaster. In extreme cases, it may be desirable to pump water from the sediment pool below the outlet invert. It should be noted that project toilets, showers, and sink fixtures are low flow or microflow types.

7-13. Deviation from Normal Operation. Deviations from normal operation are discussed in exhibit A.

7-14. Rate of Release Change. Release changes should not be made without notifying the Tule River Watermaster or his representative. There are numerous irrigation structures downstream from the dam which may require adjustments prior to any release change. In addition, during periods of high releases, the Tule River channel must be patrolled for debris removal and to assure the proper functioning of flood control works. These downstream activities are coordinated through the Tule River Watermaster.

Generally, the rate at which flows will be changed will be based on prevailing downstream conditions. In the absence of any downstream constraints, releases from Success Lake should not be increased or decreased by more than 1,000 c.f.s. per hour.

VIII - EFFECT OF WATER CONTROL PLAN

8-01. General. Success Lake has decreased the frequency of flooding, increased the water available for irrigation during the irrigation season and increased the recreation opportunities within the Tule River basin. The historical operation of Success Lake is shown graphically on plate 16.

8-02. Flood Control.

a. Spillway Design Flood. The spillway design flood for Success Lake is based on a storm averaging 23.2 inches of precipitation and the equivalent of 4.7 inches of snowmelt over the entire basin resulting in a total runoff of 16.6 inches. The total volume of runoff in 4 days is 347,000 acre-feet. The peak inflow is 200,000 c.f.s. A routing of the spillway design flood is shown on plate 17.

b. Standard Project Rainflood. The standard project rainflood shown in this manual was developed in 1970. The total average precipitation over the basin (20.14 inches) is about the same as that in December 1966 but the freezing level, snowmelt, time distribution and infiltration rates are more severe. The excess (6.12 inches) combined with base flow gives a total main wave volume of 157,000 acre-feet, about 140 percent of the 5-day runoff from 4 through 8 December 1966. A routing of the standard project rainflood is shown on plate 17.

c. Reservoir Design Flood. The reservoir design flood shown in Design Memorandum No. 5 Reservoir Regulation, dated December 1956, was considered to be a 100-year flood and was controlled to 3,200 c.f.s. below Success Dam. It was concluded that the project provided 100-year protection to agricultural areas since at that time 3,200 c.f.s. was considered non-damaging. Its 4-day volume is about 95,000 acre-feet which is about a 50-year event on the current frequency curves for unregulated rainflows below Success Dam shown on plate 19. In addition, the design flood is a 4-day flood series whereas routings show that, due to limited release schedules at low pool elevations, a longer duration series is critical at Success Lake. Success Lake was considered to provide standard project flood protection to Porterville. However, the SPF shown in D.M. No. 5 was exceeded in December 1966 and a new one was developed in 1970. Routings using 30-day rainflood series based on the frequency curves for unregulated rainflows below Success Dam indicate that Success Lake will fill to the spillway or above an average of once every 30 years, spill 3,200 c.f.s. or more once every 40 years and exceed the channel capacity through Porterville about once every 100 years. These routings were made assuming that on the average 80 percent of the scheduled releases shown on plate A-8 would be achieved. Routings of the reservoir design flood and 100-year flood are shown on plate 17.

d. Snowmelt floods. Releases required to control snowmelt floods are not expected to exceed 3,200 c.f.s. except during exceptionally rare events. Releases exceeding 1,500 c.f.s. (total downstream diversion and spreading capability above Turnbull Weir) can be expected about once every 40 years. Tule River flows below Turnbull Weir may damage Tulare Lakebed depending on their diversion capability. Hypothetical routings of the 1906 and 1969 snowmelt floods using the criteria on plate A-8 are shown on plate 18.

8-03. Recreation. Success Lake supports a fishery and provides opportunities for many other types of recreation. A description of the recreation development is in paragraph 2-06.

8-04. Water Quality. Although the agricultural and recreational activities at the lake and the warming of the ponded water may have some detrimental affect on quality, Success Lake provides water for recreation and irrigation at times when there would otherwise be none and the quality of the water is good to excellent relative to its beneficial uses. The beneficial uses are listed in table 4-12.

8-05. Fish and Wildlife. Success Lake supports an excellent warmwater fishery within the lake. This is a considerable enhancement since natural flow in the Tule River often falls to zero.

8-06. Water Supply. Success Lake provides approximately 25,000 acre-feet of new and redistributed water.

8-07. Hydroelectric Power. There is presently no generation of hydroelectric power at the project. However, there is some potential and the feasibility for power generation is presently being investigated by the Tule River Association.

8-08. Navigation. Success Lake augments Tule River flows, however, very little if any navigation occurs below the dam.

8-09. Frequencies.

a. Peak Flow Probability. The potential for rainfloods below the dam comes from project spills. There is little local flow between the dam and Porterville. Rainflow frequency curves for unregulated and regulated flows at the dam are shown on plate 19. Snowmelt flow frequency curves for unregulated and regulated conditions are shown on plate 20.

The unregulated rainflow frequency curves were based on a two station comparison between the Tule River gage below Success Dam and the Tule River near Porterville gage. The curves were then adjusted on the assumption that the 1 through 15 day flows during the December 1966 flood were the largest in the last 100 years. The curves were also adjusted for expected probability. The plotting positions for the flows below Success Dam were determined by correlation with the flows near Porterville. The period of record for the Tule River near Porterville gage is from 1901 through 1960.

The regulated rainflow frequency curve was drawn graphically. The project releases were plotted based on a period of nineteen years except for the December 1966 peak release which was plotted at the frequency of the 30-day flow for that flood. Hypothetical routings assuming 80 percent channel capacity were used to locate the uncontrolled portion of the curve. A 30-day flood series was used, the frequency of which was determined from the unregulated 30-day frequency curve.

The snowmelt flow means at the Tule River below Success Dam and the Tule River near Porterville gages were close and the correlation coefficients for the flows of various durations at these stations were .99+. So, it was felt that little error would result from estimating the snowmelt flows at Success

through a correlation with the near Porterville gage flows. The snowmelt flow frequency curves were developed by treating the estimated and actual flows below Success Dam as a continuous record. The actual flows below Success Dam were plotted as indicated by the correlation with the gage near Porterville.

The regulated snowmelt flow frequency curve was drawn graphically. The project releases were plotted based on a period of nineteen years except for the 1969 flood which was plotted as the second largest in 78 years. Hypothetical routings were used to locate the upper portion of the curve. The routings were based on the April through July 1969 flow pattern with the volume determined by the 120-day unregulated snowmelt curve. The flood control diagram and irrigation demands shown on plate A-8 were used for the routings.

b. Stage-Duration and Frequency. Stage-duration curves, a stage-frequency curve and seasonal variation of reservoir storage frequency curves are shown on plates 21, 22 and 23.

8-10. Other Studies. The Tule River association is presently investigating the feasibility of generating power with Succes Lake releases.

IX - WATER CONTROL MANAGEMENT

9-01. Responsibilities and Organization.

a. Corps of Engineers. The District Engineer, Sacramento is responsible for:

(1) Prescribing the use of flood control space in Success Lake.

(2) Operation and Maintenance of Success Lake.

(3) Advising local interests and the Division Engineer of any substantial deviation from the flood control regulations.

(4) Preparing monthly operation and other reports required by the Division Engineer.

(5) Estimating the water users share of maintenance and operation costs.

Corps personnel under supervision of Construction-Operations Division, Sacramento District, operate Success Lake with instructions on all matters pertaining to flood control operation received directly from the Reservoir Control Section. The duties of the reservoir operators and the Reservoir Control Section are discussed in detail in Exhibit A.

b. Bureau of Reclamation. The Bureau acts as the agent for the United States in the execution of the repayment contract (14-06-200-2110A).

c. California Department of Fish and Game. They enforce fish and game laws on the lake and within the wildlife areas. They also plant fish in the lake.

d. California Division of Forestry. They are responsible for fire fighting on project lands.

e. County of Tulare. They provide normal law enforcement at the project and, through an agreement with the State, patrol the lake by boat. During periods of peak visitation, they provide additional law enforcement under contract with the Corps. They also supervise and maintain Bartlett Park which is on project land below the dam.

f. Tule River Watermaster. He is appointed by the Tule River Association to act on behalf of downstream water users. He directs the use of space not required for flood control in Success Lake.

9-02. Interagency Coordination.

a. Local Press. Either the Corps of Engineers Public Affairs Office or the Tule River Association are responsible for making local press releases concerning the operation of Success Lake. The Federal-State River Forecast Center furnishes the press with downstream river flow forecasts.

b. National Weather Service. The California Department of Water Resources cooperates with the National Weather Service to develop streamflow forecasts. The Corps of Engineers provides them with forecasts of Success Lake operation.

c. U.S. Geological Survey. The Corps of Engineers makes payments to the U.S.G.S. to maintain 5 gages on the Tule River: Tule River near Springville; South Fork Tule River near Success, California; Success Lake near Success, California; Tule River below Success Dam and Pioneer Ditch below Success Dam. The U.S.G.S. publishes the flows and water quality data (when applicable) at these gages.

d. California Department of Water Resources. The Corps of Engineers furnishes the DWR with precipitation and temperature data from climatological stations it maintains on the Tule River: Hossack, Eagle Creek, Mountain Home, Rogers Camp and Success Dam. The DWR publishes most of this data.

e. Bureau of Reclamation. The Friant Kern Canal which is operated by the Bureau of Reclamation carries diverted water from Millerton Lake on the San Joaquin River to Tulare Lake Basin. The canal diverts San Joaquin River water to the Tule River irrigation network. The operation of the Friant Kern Canal and Success Lake must be coordinated. The coordination of conservation releases is normally the responsibility of the Tule River Watermaster. However, during floods, Corps personnel and Bureau personnel should be aware of how the operation of Success Lake and the Friant Kern Canal will impact the Tule River.

f. Tule River. All releases from Success Lake must be coordinated with Tule River Watermaster since he has first hand knowledge of downstream conditions and may have to operate various structures to accommodate a release change.

g. Other Local Agencies. Releases from Success Lake, which are not used for irrigation or spreading may flow to Tulare Lakebed and flood cropland. Therefore, whenever such releases are anticipated, Tulare Lake interests should be notified.

9-03. Coordination with Other Projects Operated by the Corps of Engineers. Pine Flat Lake, Lake Kaweah, and Isabella Lake are all operated by the Corps of Engineers and have the potential to release floodwater to Tulare Lakebed. The flood control operation of these projects must be coordinated with that of Success Lake to take advantage of any opportunity to minimize flood damages.

9-04. Interagency Agreements. The division of responsibilities in the Central Valley Basin of California between the Corps of Engineers and the Bureau of Reclamation in respect to water resource project planning, construction and operation activities is spelled out in the Memorandum of Agreement between the Department of The Army and The Department of the Interior on division of responsibilities in the Central Valley Basin, California dated 29 December 1958.

The provisions for payment of project first costs and O&M costs by local interests are set forth in Bureau of Reclamation contract number 14-06-200-2110A.

9-05. Commissions, River Authorities, Compacts and Committees. None.

9-06. Reports. The Tule River Association publishes an annual report listing precipitation, discharge, unit entitlement, storage, and diversion. Other reports required for the operation of Success Lake are discussed in exhibit A.

2	178

Drainage Area - 393 sq. mi.

EXAMPLE 1

FIND:

Estimated average flow on 15 January.
Estimated 10-day volume from 15 January through 24 January.

GIVEN:

Basin mean precipitation (BMP) on 14 January = 5 inches.
Average temperature at Lake Success on 14 January = 45°F.
Basin wetness parameter (PAR') for 13 January = 15 inches.

FROM CHART:

15 January flow estimate = 8,100 c.f.s.
10-day volume (15-24 Jan) = 18,100 c.f.s. days.

EXAMPLE 2

FIND:

Update 15 January through 24 January volume estimate on 17 January.

GIVEN:

Average daily flows on 15 and 16 January are 7,000 c.f.s. and 2,800 c.f.s.
BMP on 15 and 16 January equals zero.

FROM CHART:

Use 2-day volume = 9,800 c.f.s.; therefore, the updated 15-24 January volume (10 days) estimate is 15,500 c.f.s. day.

NOTE:

Computations of PAR' and BMP are found in paragraph A-3f.

STANDING INSTRUCTIONS TO DAMOPERATOR

TABLE OF CONTENTS

LIST OF PLATES

EXHIBIT A

STANDING INSTRUCTIONS TO DAMOPERATOR

A-1. General. This exhibit is prepared in accordance with instructions contained in EM 1110-2-3600, paragraph 4-07, (Standing Instructions to Damoperators) and ETL 1110-2-251 and pertains to duties and responsibilities of the damoperators in connection with the operation of Success Lake, and the reporting of required hydrologic data.

Operational instructions to the damoperator, relating to flood control, are outlined with specific emphasis on flood emergencies when communication facilities between him and the Reservoir Control Section have been disrupted. It is designed to be used independently as a flood control guide, or as published, in conjunction with the water control manual. To facilitate independent use of this appendix, plates required for flood control operation (A-1 through A-8) are included herein.

A-2. Operational Responsibilities. The primary responsibilities for operating Success Lake are delegated to units of the Engineering Division and Construction-Operations Division of the Sacramento District, U.S. Army Corps of Engineers, as outlined below. Names and telephone numbers for the individuals whose responsibilities are outlined are given at the front of this exhibit and at the front of the manual.

a. The Hydrology Section (Engineering Division).

(1) Obtaining current hydrometeorological data and weather forecasts for the region.

(2) Maintaining hydrologic equipment and supervising its operation.

(3) Supervising a program of water quality and sediment measurement.

b. The Reservoir Control Section (Engineering Division).

(1) Analyzing current reservoir and hydrologic data, determining a schedule under which the reservoir shall be operated, and issuing appropriate operating instructions (except for routine day-to-day operations for conservation only) to the reservoir operator.

(2) Preparing monthly operation and other special reports relative to the operation of the reservoir.

(3) Advising the District Engineer through the Chief of Engineering Division whenever there has been an unavoidable departure from these operating rules, or when there is a need for making temporary modification of these operating rules.

(4) Keeping advised at all times of channel and seepage conditions in downstream channels and spreading areas. This will require periodic inspections during years of high runoff.

(5) Maintain a record of nonscheduled operation changes requested by the watermaster and other agencies.

(6) Making necessary revisions to this Water Control Manual and distributing them.

c. The Park Manager (Construction-Operations Division).

(1) Keeping well informed of the operating rules contained in this Water Control Manual and bringing to the attention of the Reservoir Control Section any feature of the manual that may require clarification or revision.

(2) Keeping familiar with the operation of all recording and communication equipment.

(3) Accomplishing the physical operation of the reservoir in accordance with instructions contained in the Water Control Manual or issued by the Reservoir Control Section.

(4) Calculating and maintaining a record of inflows, outflows, storage, weather data, and other data specified by the Reservoir Control Section.

(5) Reporting, by radio or telephone to the Reservoir Control Section, data outlined in this exhibit.

(6) Obtaining necessary information on scheduled downstream irrigation and spreading activities and keeping local interests continuously advised of the routine operation of the reservoir.

(7) Reporting to the Reservoir Control Section any unusual conditions which might interfere with the planned operation of the reservoir.

(8) Maintaining a log of outlet gate operation containing any change in gate position, date, time, and water surface elevation when such changes were made, and initials of the individual accomplishing the change.

(9) Making and recording weekly checks on reservoir and outflow gage readings to assure proper operation of all recording equipment.

(10) Obtaining samples for water quality and sedimentation analysis as required.

(11) Immediately after the end of each month, transmitting to the Reservoir Control Section data specified under reports in paragraph A-6.

(12) Making emergency operation changes when contact with the Reservoir Control Section is broken and a clearly defined change occurs that warrants immediate action.

(13) Maintaining a record of instructions received from the Reservoir Control Section, and requests received from the Tule River Watermaster.

A-3. Computation of Hydrologic Data. During normal operation the following computations are made daily by the indicated personnel.

Reservoir Control Section	Reservoir Operator
Basin Mean Precipitation	Releases from the Reservoir
Basin Wetness Parameter	Inflow to the Reservoir
Evaporation from the Reservoir	Evaporation from the Reservoir
Inflow to the Reservoir	

During emergencies, these computations may be made more frequently as directed by the Reservoir Control Section. The basin mean precipitation, the basin wetness parameter and the reservoir inflow are computed on the HADA computer. Forms are available from the Reservoir Control Section to facilitate manual computations.

a. Mean Daily Releases from the Reservoir.

(1) Check punch tape for errors in gage height and for time. Time is corrected to the current 15 minutes; gage height to the nearest .01 foot.

(2) Tabulate correct gage height readings at odd hours, starting with 0100 hours. Punch tape correction, if any, should be noted.

(3) Enter current rating table, using shifts as applicable, determine and list flow at each odd hour, using the procedure indicated for mean daily flow in (6) below.

(4) Total the 12 flow readings so obtained and divide by 12. This is the mean daily flow.

(5) Mean daily flow will be listed to nearest 0.1 c.f.s. for flows up to 10 c.f.s., and to the nearest 1 c.f.s. for flows above 10 c.f.s. Such values will later be rounded to 3 significant figures by the USGS prior to publication.

(6) When calculating discharge from gage height with a (-) shift correction, enter rating table below the actual height, i.e., if observed gage height is 4.86 and shift is -.02, enter rating table at 4.84 to obtain discharge. For (+) shift, enter rating table above observed gage height.

(7) In order to calculate the gage height for a desired flow under a (-) shift condition, add amount of (-) shift to gage height obtained from table for desired discharge, i.e., if shift is -.03, desired discharge is 5,000 c.f.s., and the rating table shows a gage height of 10.20 = 5,000 c.f.s., the required gage height for 5,000 c.f.s. is 10.20 + .03 = 10.23. For (+) shift, subtract amount of shift from gage height obtained from table for desired discharge.

b. Evaporation from the Reservoir. Lake evaporation in inches is equal to the pan evaporation in inches multiplied by the evaporation coefficient shown on plate A-6. For this computation, pan evaporation measured at 7:00 a.m. is used to compute lake evaporation for the previous day:

Pan evaporation (inches)

x Gross Evaporation Coefficient
12
x Average Lake Area (acres) = acre-feet
(Round to nearest acre-foot for next computation)
acre-feet x 0.50417* = s.f.d. = mean c.f.s. for 24-hours.

*Coefficient shown is for 24-hour day. When changing to daylight savings time or from daylight savings time the coefficients are as follows: for 23-hour day (change to D.S.T.) use 0.52609; for 25-hour day (change from D.S.T.) use 0.48400.

Lake area used when computing evaporation will be the average area for the day; obtained by averaging the midnight areas at the beginning and ending of the period being computed.

c. Inflow to the Reservoir. Computed mean inflow to the lake will be taken as the algebraic sum of the mean outflow, change in lake storage, and evaporation for the lake water surface and will represent mean inflow to the lake from all sources including rainfall on the lake surface.

Mean Daily Outflow (c.f.s.) +
Change in Lake Storage (s.f.d.)+
Evaporation (s.f.d.) =
Mean Inflow (c.f.s.)

d. Basin Mean Precipitation. The approximate basin mean precipitation (BMP) is computed by multiplying the sum of the precipitation at representative rain gages by the conversion factor for the basin and gages. The conversion factor is computed by dividing the basin normal annual precipitation (BNAP) by the sum of the station normal annual precipitation (SNAP)). The computation of the conversion factor (C) for the Tule River Basin and the rain gages normally observed is shown below:

Gage	SNAP
Hossack	42"
Eagle Creek	36"
Rogers Camp	36"
Mountain Home	38"
Success Dam	11"
Sum SNAP	163"

BNAP = 31"

Basin Conversion Factor (C) = 31"/163" = 0.19

e. Basin Wetness Parameter. The basin wetness parameter (PAR) for a given day is the basin mean precipitation (BMP) for that day plus 97 percent

of the previous day's wetness parameter (PAR') and is represented by the equation PAR = BMP + .97 PAR'. A sample computation of PAR is shown in paragraph A-3f.

f. Encroachment. As part of Success Lake's drought contingency plan, Schedule 1 releases may be deferred temporarily during the period 10 November to 1 April to allow storage of 3,200 acre-feet in Schedule 1 space above elevation 588.9 feet subject to the following: The amount of encroachment (E) above elevation 588.9 feet will be dependent on the basin wetness parameter (PAR) and will vary proportionately from 3,200 acre-feet when PAR is 2 inches or less to 0 acre-feet when the PAR Is 6 inches or more. Values of E and PAR are shown in tabular form below along with an example computation.

EXAMPLE

Given:
Station precipitation for 14 January

Success Dam	1.69 in.
Mountain Home	5.00 in.
Rogers Camp	4.40 in.
Eagle Creek	8.80 in.
Hossack	6.40 in.

Data for BMP, PAR and E for the period 8 Jan through 13 Jan.

Date	BMP (in.)	.97 PAR' (in.)	PAR (in.)	E (ac-ft)
8 Jan	0.20	1.56	1.76	3,200
9 Jan	2.00	1.71	3.71	1,832
10 Jan	2.22	3.60	5.82	144
11 Jan	0.50	5.65	6.15	0
12 Jan	1.00	5.97	6.97	0
13 Jan	8.24	6.76	15.00	0
14 Jan	(5.00)	(14.55)	(19.55)	(0)

Basin conversion factor (C) = BNAP/SNAP = 31"/163" = 0.19

Find:

BMP, PAR and E for 14 January.
BMP = C (13.29) = 0.19 (13.29) = 5.00 in.

PAR = BMP + .97 (PAR') = 5.00 + .97 (15.00) = 19.55 in.
(PAR' = previous day's PAR)

E = [6-PAR)/4] 3,200 acre-feet = 0 acre-feet
(E = 0 acre-feet when PAR = 6 in.)

A-4. Outlet Gate Operation. Desired releases through each outlet will be obtained by manipulating the gates until the appropriate stages are obtained as indicated by the current rating curve for Pioneer Ditch (plate A-5) and the current rating curve for the Tule River (plate A-5). The partial gate opening curves on plate A-3 will be used as a guide in estimating gate openings for river outlet releases. Releases to Pioneer Ditch will be regulated by the 42" double disc type gate valve. Other irrigation releases and flood releases below the spillway level will be regulated by the two 5'8" x 10'0" hydraulically operated slide gates. There are no hydraulic limitations on the sequence or arrangement of openings for these two slide gates. However, for larger releases, it is desirable to maintain approximately equal gate openings at the two gates whenever feasible in order to obtain smooth flow through the conduit. Operation of outlets when spillway flows are occurring is described in paragraph A-8.

A-5. Normal Flood Control Operation. Plate A-8 depicts flood control space and flood control release requirements.

a. All inflow in excess of the releases requested by the Tule River irrigation interests will be stored to the extent that conservation space is available.

b. Release of water stored for irrigation will be in accordance with the requests of the Tule River Watermaster, conforming with mutual agreements and stipulations of the water users, unless prior release is required for flood control.

A-6. Reports. The damoperator shall report the following data by radio or telephone to the Reservoir Control Section each work day between 7:30 a.m. and 9:00 a.m.:

a. Reservoir stage as of midnight.

b. Pan evaporation as of 7:00 a.m.

c. Mean daily flows (ending at midnight) of:

(1) Tule River below Success Dam.

(2) Pioneer Ditch below Success Dam

d. Daily precipitation at the dam as measured at 7:00 a.m.

e. Climatological gage readings for precipitation at Eagle Creek, Rogers Camp, Hossack and Mountain Home.

When conditions do not warrant weekend or holiday reports, complete reports for each day shall be made on the first day following the non-reporting period. More frequent reports of the above information and reports of other Tule River data will be made in the same manner when requested by the Reservoir Control Section. Forms furnished to the operators are to be used in computing the above information.

Immediately after the end of each month, the reservoir operator will dispatch to the Reservoir Control Section all original forms used for observations and computations as specified above. The charts and punch tapes for that month from the following instruments will be included.

a. Recording precipitation gage of Success Lake.

b. Recording Hygrothermograph at Success Lake.

c. Reservoir level recorder punch tape.

d. Stream gages below dam on the Tule River and on Pioneer Ditch.

A-7. Special Weather and Flood Reports. During the rain flood season from 1 October to 1 May the damoperator shall call the Reservoir Control Section whenever any of the following occurs:

a. One inch or more of rainfall at the project or at any of the radio-reporting precipitation stations during any 6-hour period or 1.5 inches or more of rainfall during any 24-hour period.

b. An increase in flow at the main Tule River inflow station of 1,000 c.f.s. or more during any 6-hour period.

Any special report based on one of the foregoing criteria should include the latest available data concerning the other item. On nonworking days or at night, these special reports should be telephoned directly to the Chief of the Reservoir Control Section or his designated representative.

A-8. Standing Instructions During Flood Emergency. Flood control operation shall be in accordance with instructions from the Reservoir Control Section. During flood periods, close contact will be maintained between project and District personnel on a 24-day per day basis or as otherwise required.

If communication is broken between the operating personnel and the Sacramento District Office during a flood emergency, continue releases in accordance with the last instructions received from the Sacramento District unless a clearly defined change occurs that warrants immediate action. Every attempt should be made to reestablish communications.

The maximum design release of 3,200 c.f.s. will not be intentionally exceeded. If flow over the spillway occurs, gate releases will be curtailed so as to maintain a flow of 3,200 c.f.s. or less for as long as possible.

A-9. Emergency Notification. For serious emergencies when large spillway releases or dam failure are eminent, an emergency notification plan is maintained at the Success Lake Project Office. The park manager is responsible for implementing the emergency notification plan; however, such notification should be coordinated with the Reservoir Control Section, if possible.

A-10. Modification of Regulations. The reservoir operator may make emergency departures from the regulations in this manual as required by operating equipment failures, accidents such as drownings or other emergencies that require immediate action. The Reservoir Control Section of the Army Corps of Engineers, Sacramento District should be notified of such departures as soon as possible. The District Engineer, Sacramento District, U.S. Army Corps of Engineers may make temporary modifications to these regulations. Permanent changes are subject to approval by the Division Engineer, South Pacific Division, U.S. Army Corps of Engineers.

TULE RIVER, CALIFORNIA

DISCHARGE RATING CURVE

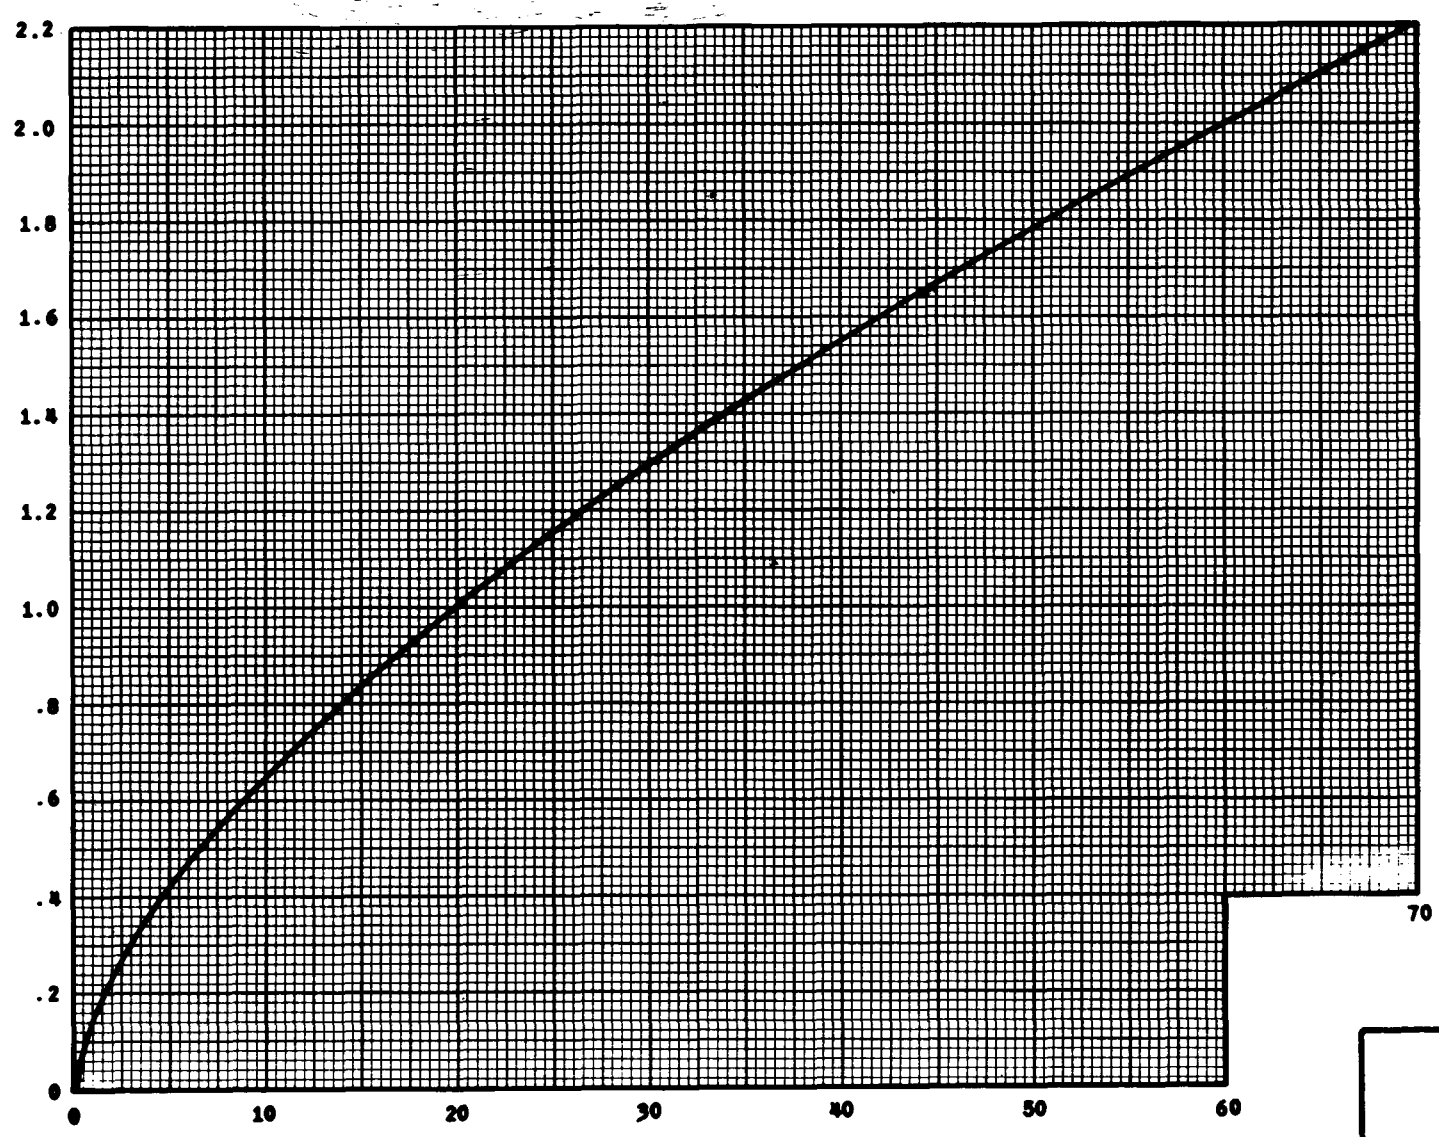
TULE RIVER BELOW SUCCESS DAM

CORPS OF ENGINEERS, SACRAMENTO, CALIFORNIA

Prepared: L.H.C.
Drawn: L.H.C.
Date: JULY 1980



From U.S.G.S. rating table No.2 printed 18 June 1980.

SUCCESS LAKE
TULE RIVER, CALIFORNIA

DISCHARGE RATING CURVE

PIONEER DITCH

CORPS OF ENGINEERS, SACRAMENTO, CALIFORNIA

Prepared: L.H.C.
Drawn: L.H.C.
Date: APRIL 1980

SHEET 4 OF 4 PLATE A-6

DIVERSIONS AND CAPACITIES

	CANAL OR DITCH	CAPACITY (c.f.s.)
1	Pioneer Ditch	35
2	Campbell-Moreland	30
3	Porter Slough	180
4	Porter Slough Ditch	20
5	Vandalia Ditch	9
6	Poplar Ditch	150
7	Hubbs-Miner Ditch Rhodes and Fine Ditch	25 a/
8	Woods-Central Ditch (Woods-Central Canal) Stockton Ditch Little Pioneer Ditch	250 b/ b/
9	North Canal	300
	SUBTOTAL	999
10	East Branch Lakeland Canal	c/ 300
11	Taylor Ditch	65
	GRAND TOTAL	1,364

a/ Rhodes and Fine Ditch has been combined with Hubbs-Miner Ditch and Poplar Ditch.

b/ Stockton Ditch and Little Pioneer Ditch have been combined with Woods-Central Ditch.

c/ Canal enlargement to 550 c.f.s. under construction.

DOWNSTREAM CHANNEL CAPACITIES

CORPS OF ENGINEERS, SACRAMENTO, CALIFORNIA

Prepared: L.H.C. Date: MAY 1981

PLATE A-7

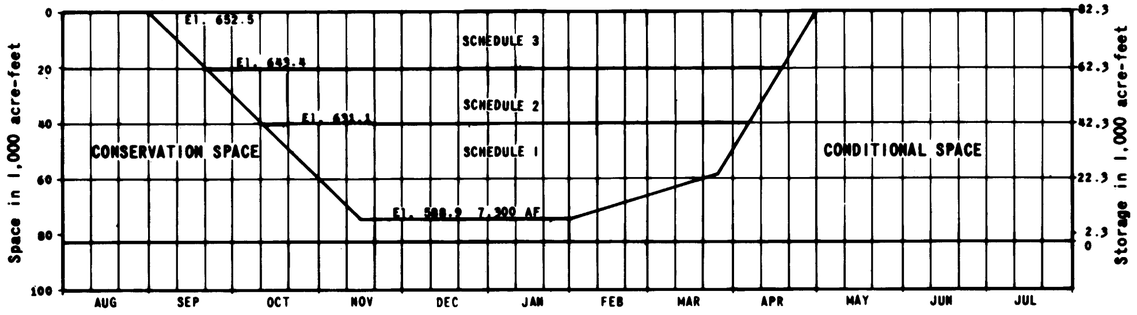

FIGURE 1

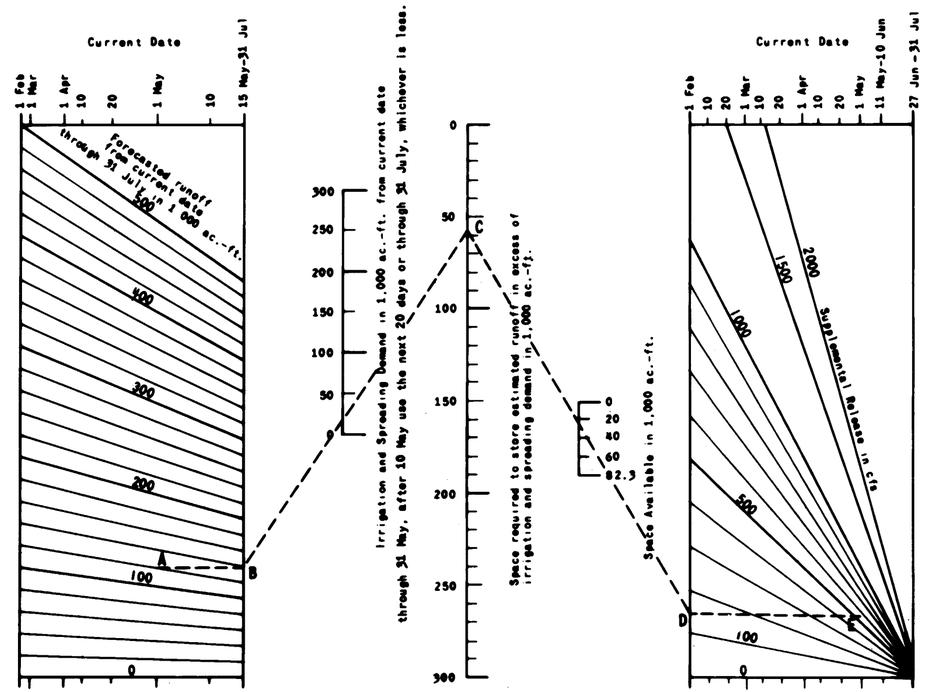

FIGURE 2

USE OF DIAGRAM

1. Water stored in conservation space will be released as requested by the Tule River watermaster.

2. Water stored in Schedule 1, 2 or 3 space will be released in accordance with the schedule that applies to that space.

3. Schedule 1 releases may be deferred temporarily during the rainflood period 11 November through 27 March to allow storage of 3,200 acre-feet in schedule 1 space, subject to the following. The limit on storage (S) in schedule 1 space will be dependent on the basin wetness parameter (Par) and will vary incrementally from 3,200 acre-feet when Par is 2 inches or less, to 0 acre-feet when Par is 6 inches or more. Values of Par and S are shown in tabular form below. The computation of Par is discussed in Exhibit A paragraph 3f.

Basin Wetness Parameter (Par) (inches)	Storage (S) (acre-feet)
Less than 2.00	3,200
2.01 to 3.00	2,800
3.01 to 4.00	2,000
4.01 to 5.00	1,000
5.01 to 6.00	400
More than 6.00	0

Calculation of Par will begin with Par = 0 at midnight on 31 August of each year.

4. Water stored in conditional space that is required for flood control must be released as a supplemental release in addition to releases for irrigation and spreading. The conditional space required for flood control is equal to the space required to store estimated runoff in excess of demand for irrigation and spreading. The space and supplemental release can be determined from figure 2.

5. Estimates of future inflow, for release computations, will be made by the Corps of Engineers.

6. The Corps of Engineers may direct that flood control space and releases be increased or decreased from those required by this diagram based on conditions prevailing at the time.

SCHEDULE 1

Water stored in schedule 1 space will be released at the lesser of A,B,C or D below.

SCHEDULE 2

Water stored in schedule 2 space will be released at the lesser of C or D below.

SCHEDULE 3

Water stored in schedule 3 space will be released in accordance with D below or at a lesser rate determined by the Corps of Engineers.

A. The estimated release which will evacuate the encroachment plus inflow within the next 5 days. The estimated release shall be maintained for five days unless the desired stage is achieved in less time or inflow is greater than anticipated and a greater release is required.

B. The release required to provide a quantity of water arriving at Turnbull Weir no greater than the quantity of water requested by the Tulare Lake interests for irrigation , spreading and flood control.

C. The "base release" from figure 3 plus the estimated average inflow for the next 5 days. The computed release shall be maintained for 5 days unless the desired stage is achieved in less time or inflow is greater than anticipated and a greater release is required.

D. The "maximum release" specified in figure 3.

SAMPLE CONDITIONAL SPACE COMPUTATION

Given Data:

Date.....1 May
Forecasted runoff from 1 May through 31 July.....120,000 acre-feet
Forecasted irrigation and spreading demand from 1 May through 31 May.....18,450 acre-feet
Irrigation and spreading demand on 1 May.....250 c.f.s.
Space available in Success Lake.....25,000 acre-feet

Computation of Space Required to Store Runoff Exceeding Irrigation and Spreading Demand:

Enter Figure 2 at "A" with current date (1 May) and forecasted runoff from current date through 31 July (120,000 acre-feet) and move horizontally to "B".

From "B" extend a line through the irrigation and spreading demand (18,450 acre-feet) to "C" and read the space required to store the runoff exceeding irrigation and spreading demand (57,600 acre-feet).

Computation of Supplemental Release:

Extend a line from "C" through the space available (25,000 acre-feet) to "D".

From "D" move horizontally to "E" below the current date (1 May) and read the supplemental release (550 c.f.s.).

Computation of Total Release:

Add the supplemental release (550 c.f.s.) to the irrigation and spreading release (250 c.f.s.) to get a total release of 800 c.f.s..
